

Introduction to K-Nearest Neighbors: Takeaways

by Dataquest Labs, Inc. - All rights reserved © 2020

Syntax

- Randomizing the order of a DataFrame:

```
import numpy as np

np.random.seed(1)

np.random.permutation(len(dc_listings))
```

- Returning a new DataFrame containing the shuffled order:

```
dc_listings = dc_listings.loc[np.random.permutation(len(dc_listings))]
```

- Applying string methods to replace a comma with an empty character:

```
stripped_commas = dc_listings['price'].str.replace(',', '')
```

- Converting a Series object to a float datatype:

```
dc_listings['price'] = dc_listings['price'].astype('float')
```

Concepts

- Machine learning is the process of discovering patterns in existing data to make a prediction.
- In machine learning, a feature is an individual measurable characteristic.
- When predicting a continuous value, the main similarity metric that's used is Euclidean distance.
- K-nearest neighbors computes the Euclidean Distance to find similarity and average to predict an unseen value.
- Let x to represent the feature values for one observation, and y to represent the feature values for the other observation then the formula for Euclidean distance is as follows:

- In the case of one feature (univariate case), the Euclidean distance formula is as follows:
